

SEMICONDUCTOR INTEGRATED CIRCUIT DEVICE AND MANUFACTURING METHOD THEREOF

CROSS-REFERENCE TO RELATED APPLICATIONS

5 This application is a continuation of application Serial No. 10/227,799 filed on August 27, 2002, which is a continuation of application Serial No. 09/446,302 filed on April 14, 2000, now issued as U.S. Patent No. 6,483,136. The contents of application Serial Nos. 10/227,799 and 09/446,302 are hereby incorporated herein by reference in their entirety.

TECHNICAL FIELD

10 The present invention relates generally to semiconductor integrated circuit devices and manufacturing architectures of the same. More particularly, but not exclusively, the invention relates to those technologies which are adaptable for use with semiconductor integrated circuit devices having dynamic random access
15 memory ("DRAM") modules.

BACKGROUND OF THE INVENTION

 Currently available DRAMs are typically designed to include an array
20 consisting of rows and columns of memory cells disposed in a matrix form on a principal surface of a semiconductive substrate at cross points or "intersections" between a plurality of word lines and a plurality of bit lines, wherein each of the memory cells consists essentially of a capacitive element for accumulation of information and a metal insulator semiconductor field effect transistor (MISFET) for
25 use in selecting a single memory cell, which MISFET is serially connected to the

capacitive element. The memory cell selecting MISFET is formed in an active region of the semiconductor substrate which is surrounded at its periphery by an element separation or isolation region. The MISFET is generally designed to consist of a gate oxide film and a gate electrode integral with a corresponding one of the word lines, plus a pair of semiconductor active regions for use as a source and drain of the transistor. A bit line is disposed to overlie the memory cell selecting MISFET in a manner such that it is electrically connected to one of the source and drain which is commonly shared by two memory cell selection MISFETS. The information accumulation capacitive element is laid out at a location overlying the memory cell select MISFET and is electrically coupled to the remaining one of the source and drain.

A DRAM device having a memory cell structure of this type has been disclosed in Published Unexamined Japanese Patent Laid-Open No. 5-291532 and other publications. The memory cells of the DRAM as disclosed therein are designed so that word lines are increased in width or made "fat" in active regions (the regions in each of which a word line serves as the gate electrode of a memory cell select MISFET) and reduced in width or "thinned" in the remaining regions in order to retain the required gate length when miniaturizing or "downsizing" the memory cell select MISFETs, while at the same time minimizing the pitch of word lines.

In addition, the DRAM memory cells as described by the Japanese Application referred to above is arranged so that the bit lines are partly fattened to extend up to those portions overlying the active regions and a planar pattern of such active regions is designed into a gull-wing shape with part of it being bent toward the

bit line side in order to achieve successful electrical conduction of more than one contact hole for use in connecting between one of the source and drain of a memory cell select MISFET and its corresponding bit line operatively associated therewith.

Regrettably the DRAM memory cells described by the above Japanese

- 5 Application has the inherent problem of being unable to provide any excellent size/dimension accuracy when partly increasing the widths of word lines and bit lines or when employing the gullwing-shaped planar pattern of the active regions, due to the fact that presently available photolithography techniques suffer from difficulties in accurately achieving ultra-fine resolution of curved-line patterns and/or folded-line
- 10 patterns in cases where the minimal fabricatable size becomes at or near a limit of resolution in photolithography processes as a result of further progress in microfabrication or miniaturization of such memory cells. Another problem inherent in the prior art DRAM device is that as a through-going hole for use in connecting between the lower-side electrode of an information accumulation capacitive element
- 15 and the remaining one of the source and drain of its associated memory cell select MISFET is inherently disposed between one bit line and another bit line, so that partly fattening the bit lines makes it difficult to attain the intended through-hole opening margin, which leads to an inability to assure elimination of unwanted electrical short-circuiting between the lower-side electrode within a through-hole and
- 20 its associative one of the bit lines.

It is therefore an object of the present invention to provide a specific technique for enabling achievement of further miniaturization of memory cells of a DRAM.

The foregoing and other objects and inventive features of this invention will

become more apparent from the following description and accompanying drawings.

SUMMARY OF THE INVENTION

Some representative aspects of the present invention as disclosed herein will
5 be explained in brief below.

(1) A semiconductor integrated circuit device incorporating the principles of the invention is arranged to have a plurality of word lines extending in a first direction on a principal surface of a semiconductive substrate, a plurality of bit lines extending in a second direction at right angles to the first direction, and an array of memory cells
10 of a DRAM as disposed at cross points of said word lines and said bit lines, each said memory cell including a serial combination of a memory cell selecting MISFET with a gate electrode integrally formed with a corresponding one of said word lines and a capacitive element for information accumulation, wherein said plurality of word lines are arranged to linearly extend in the first direction on the principal surface of
15 said semiconductive substrate with an identical width, and wherein a distance between adjacent ones of said word lines is less than said width.

(2) The semiconductor integrated circuit device of the invention is formed such that the distance between the adjacent ones of said gate electrodes is set at a minimal size as determined by a resolution limit of photolithography.

20 (3) The semiconductor integrated circuit device of the invention is formed such that said word lines and the gate electrode of said memory cell selecting MISFET integrally formed with a corresponding one of said word lines are comprised of a conductive film at least partially including a metallic film therein.

(4) The semiconductor integrated circuit device of the invention is formed such

that said semiconductive substrate has an active region with said memory cell selecting MISFET formed therein and being arranged to have an island-like pattern extending in the second direction on the principal surface of said semiconductive substrate while having its periphery surrounded by an element isolation region.

5 (5) The semiconductor integrated circuit device of the invention is formed such that the element isolation region surrounding said active region is formed of an element separation groove having a dielectric film embedded therein as defined in the principal surface of said semiconductive substrate.

(6) The semiconductor integrated circuit device of the invention is formed such
10 that said bit lines are formed to overlie said memory cell selecting MISFET with an insulative film laid therebetween, wherein a contact hole for electrical connection between one of a source and drain of said memory cell selecting MISFET and a corresponding one of said bit lines is formed in self-alignment with the gate electrode of said memory cell selecting MISFET.

15 (7) The semiconductor integrated circuit device of the invention is formed such that said information accumulation capacitive element is formed to overlie said memory cell selecting MISFET with an insulative film laid therebetween, wherein a contact hole for electrical connection between the other of the source and drain of said memory cell selecting MISFET and one electrode of said information
20 accumulation capacitive element is formed in self-alignment with the gate electrode of said memory cell selecting MISFET. (8) The present invention also provides

a semiconductor integrated circuit device comprising a plurality of word lines extending in a first direction on a principal surface of a semiconductive substrate, a plurality of bit lines extending in a second direction at right angles to the first

direction, and an array of DRAM memory cells disposed at intersections of said word lines and said bit lines, each said memory cell including a serial combination of a memory cell selecting MISFET with a gate electrode integrally formed with a corresponding one of said word lines and a capacitive element for information

5 accumulation, wherein said bit lines linearly extend in the second direction on the principal surface of said semiconductive substrate with an identical width and wherein distance between adjacent ones of said bit lines is greater than said width.

(9) The semiconductor integrated circuit device of the invention is formed such that the width of each said bit line is equal to or less than a minimal size

10 determinable by a resolution limit of photolithography.

(10) The semiconductor integrated circuit device of the invention is formed such that said bit lines are comprised of a conductive film at least partially containing a metallic film.

(11) The invention further provides a semiconductor integrated circuit device

15 comprising a plurality of word lines extending in a first direction on a principal surface of a semiconductive substrate, a plurality of bit lines extending in a second direction at right angles to the first direction, and an array of DRAM memory cells disposed at intersections of said word lines and said bit lines, each said memory cell including a serial combination of a memory cell selecting MISFET with a gate electrode

20 integrally formed with a corresponding one of said word lines and a capacitive element for information accumulation, wherein an active region with said memory cell selecting MISFET formed therein is arranged to have an island-like pattern extending in the second direction on the principal surface of said semiconductive substrate while having its periphery surrounded by an element isolation region,

wherein said plurality of word lines extend along the first direction on the principal surface of said semiconductive substrate with an identical width at a distance between adjacent ones thereof, wherein a certain one of said bit lines being formed to overlie said element isolation region with a first insulative film laid therebetween
5 extends in the second direction on the principal surface of said semiconductive substrate with an identical width at a regular distance, and wherein a first contact hole for electrical connection between one of a source and drain of said memory cell selecting MISFET formed in said active region and its associative one of said bit lines formed to overlie said element isolation region has a diameter in the first
10 direction greater than in the second direction, with part thereof arranged to extend to overlie said element isolation region.

(12) The semiconductor integrated circuit device of the invention is formed such that said first contact hole includes a polycrystalline silicon film formed therein, wherein said polycrystalline silicon film is doped with a chosen impurity equal in
15 conductivity type to the source and drain of said memory cell selecting MISFET.

(13) The semiconductor integrated circuit device of the invention is formed such that the corresponding one of said bit lines and said one of the source and drain of said memory cell selecting MISFET are electrically connected together via a first through-hole formed in a second insulative film sandwiched between said bit lines
20 and said first insulative film.

(14) The semiconductor integrated circuit device of the invention is formed such that the width of said bit lines is less than a diameter of said first through-hole.

(15) The semiconductor integrated circuit device of the invention is formed such that said first contact hole has a diameter in the first direction greater than in the

second direction, where a portion of the contact hole consists essentially of a first region extending to overlie said element isolation region and a second region formed beneath said first region to have a diameter in the first direction and a diameter in the second direction being substantially equal thereto, wherein said first region is
5 formed to overlie said memory cell selecting MISFET.

(16) The semiconductor integrated circuit device of the invention is formed such that said information accumulation capacitive element is formed over said bit lines with a third insulative film laid therebetween and is electrically connected to a remaining one of the source and drain of said memory cell selecting MISFET via a
10 second through-hole formed in said third insulative film and a second contact hole as formed in said first insulative film at a location underlying said second through-hole.

(17) The semiconductor integrated circuit device of the invention is formed such that said second contact hole includes a polycrystalline silicon film being embedded
15 therein and doped with an impurity equal in conductivity type to the source and drain of said memory cell selecting MISFET.

(18) The semiconductor integrated circuit device of the invention is formed such that said second through-hole is disposed between neighboring ones of said bit lines and is formed in self-alignment therewith.

20 (19) A semiconductor integrated circuit device of the present invention comprises: an array of memory cells each including a serial combination of a MISFET for memory cell selection having a source and drain plus an insulated gate electrode and a capacitive element for data storage having first and second electrodes with a dielectric film laid therebetween; word lines including first, second and third lines

extending in a first direction on a principal surface of a semiconductive substrate and each having a part used as the gate electrode of its associated memory cell selecting MISFET; and, bit lines including first and second lines disposed adjacent to each other to extend in a second direction at right angles to the first direction on the principal surface of the semiconductive substrate, wherein the first to third word lines are substantially identical in width to one another, the distance between the first word line and the second word line neighboring thereto is substantially equal to the distance between the second word line and the third word line next thereto, the distance is less than the width, the first and second bit lines are substantially the same as each other in width, which is greater than the width of these bit lines.

(20) The semiconductor integrated circuit device of this invention further comprises a first conductive layer provided between the first and second word lines for connecting the first bit line to either one of the source and drain of the memory-cell selecting MISFET and a second conductive layer laid between the second and third word lines for connecting the remaining one of the source and drain of the memory-cell selecting MISFET to the first electrode of the data storage capacitive element, wherein the aforesaid one of the source and drain of the memory-cell selecting MISFET and the first conductive layer are in self-alignment with the first word line and the second word line whereas the remaining one of the source and drain of the memory-cell selecting MISFET and the second conductive layer are self-aligned with the second word line and the third word line.

(21) The invention further provides a method of manufacturing a semiconductor integrated circuit device comprising a plurality of word lines extending in a first direction on a principal surface of a semiconductive substrate, a plurality of bit lines

extending in a second direction at right angles to the first direction, and an array of DRAM memory cells disposed at intersections of said word lines and said bit lines, each said memory cell including a serial combination of a memory cell selecting MISFET with a gate electrode integrally formed with a corresponding one of said word lines and a capacitive element for information accumulation, said method
5 comprising the steps of:

(a) forming on the principal surface of said semiconductive substrate of a first conductivity type an element isolation region and an active region of island-like pattern having its periphery surrounded by said element isolation region and
10 extending along the second direction on the principal surface of said semiconductive substrate;

(b) patterning a first conductive film formed over the principal surface of said semiconductive substrate to form word lines extending in the first direction on the principal surface of said semiconductive substrate to have the distance between
15 adjacent ones thereof less than the width of each said word line; and

(c) forming a source and a drain of said memory cell selecting MISFET by introducing an impurity of a second conductivity type into the principal surface of said semiconductive substrate.

(22) In the semiconductor integrated circuit device manufacturing method of the
20 present invention, the gate electrodes are fabricated so that the distance between adjacent ones thereof is set at a minimal size determinable by a resolution limit in photolithography.

(23) The semiconductor integrated circuit device manufacturing method is arranged to include, after said step (c), the further process steps of:

(d) forming a first insulative film overlying said memory cell selecting MISFET and then forming a second insulative film overlying said first insulative film and being different in etching rate from said first insulative film;

5 (e) etching those portions of said second insulative film overlying the source and drain of said memory cell selecting MISFET under a condition that the etching rate of said second insulative film with respect to said first insulative film becomes greater and then etching said first insulative film overlying the source and drain of said memory cell selecting MISFET to thereby form a first contact hole overlying one of said source and drain in self-alignment with said gate electrode to
10 have a diameter in the first direction greater than a diameter in the second direction with part of said first contact hole extending toward said element isolation region while forming a second contact hole overlying a remaining one of the source and drain in self-alignment with said gate electrode and having a diameter in the first direction which is substantially the same as its diameter in the second direction;

15 (f) after having embedded a conductive film in said first contact hole and said second contact hole, forming a third insulative film overlying said second insulative film and then forming a first through-hole in said third insulative film at a portion overlying a specified region extending to said element isolation region of said first contact hole; and

20 (g) patterning a second conductive film which is formed to overlie said third insulative film to thereby form bit lines extending along the second direction on the principal surface of said semiconductive substrate with an identical width at a distance between adjacent ones of said bit lines being greater than said width, and then electrically connecting together said first contact hole and a corresponding one

of said bit lines via said first through-hole as formed in said third insulative film.

(24) The semiconductor integrated circuit device manufacturing method provides that the width of said bit lines is formed to be equal in dimension to or less than a minimal size determinable by a photolithography resolution limit.

5 (25) The semiconductor integrated circuit device manufacturing method is arranged to include, after said step (g), the further steps of:

(h) forming a fourth insulative film overlying said bit lines and then forming a fifth insulative film overlying said fourth insulative film at an etching rate different from that of said fourth insulative film;

10 (i) after having etched said fifth insulative film at a portion overlying said second contact hole under a condition that the etching rate of said fifth insulative film relative to said fourth insulative film is greater, etching said fourth insulative film at a portion overlying said second contact hole to thereby form a second through-hole overlying said second contact hole in self-alignment with a corresponding one of
15 said bit lines; and

(j) patterning a third conductive film which is formed to overlie said fifth insulative film so as to form a lower side electrode of an information accumulation capacitive element which is electrically connected to said second contact hole via said second through-hole.

15 **BEST MODE FOR CARRYING OUT THE INVENTION**

Several preferred embodiments of the present invention will be described in detail with reference to the accompanying drawings. Note that in the following description, like reference characters are used to designate like parts or components with similar functionalities and any repetitive explanation will be eliminated for
20 purposes of brevity.

(Embodiment 1)

Fig. 1 is a diagram illustrating electrical equivalent circuitry of a dynamic random access memory (DRAM) device in accordance with one embodiment of the present invention. As shown herein, the DRAM chip includes a memory array

(MARY) that is configured from a plurality of memory cells (MC) organized into a matrix form at those intersections between a plurality of word lines WL (WL_{n-1}, WL_n, WL_{n+1}...) and a plurality of bit lines BL. A single memory cell for storing therein a 1-bit information or data is comprised of a serial combination of a
5 capacitive element C for information accumulation and a metal insulator semiconductor field effect transistor (MISFET) Qs for memory cell selection. The memory-cell selecting MISFET Qs has a source and a drain, one of which is electrically connected to the information accumulation capacitive element C and the other of which is electrically coupled to a corresponding one of the bit lines BL. The
10 word lines WL are connected at certain ends thereof to a word driver circuit WD, whereas the bit lines BL are coupled at their selected ends to sense amplifier circuits SA operatively associated therewith.

Fig. 2 is a diagram schematically depicting an enlarged plan view of part of the memory array integrated on the semiconductor substrate; Fig. 3 is an enlarged
15 plan view of part of Fig. 2; Fig. 4(a) shows a cross-sectional view as taken along line A-A' of Fig. 3, and Fig. 4(b) shows a sectional view along line B-B' of Fig. 3. Note that Fig. 2 and Fig. 3 indicate only those conductive layers (except plate electrodes) which make up the memory cells, while illustration of any dielectric films between conductive layers and on-chip leads overlying the memory cells is not included
20 therein.

The memory cells of the DRAM are each formed in a p-type well 2 that is formed on the principal surface of a semiconductive substrate 1 of p-type conductivity. The planar size of each memory cell is, for example, 0.46 μm x 0.46 μm. Although not a limitation of the invention, the p-type well 2 with the memory

cell formed therein (memory array) is electrically separated from the p-type semiconductor substrate 1 by an n-type semiconductor region 3 that is formed beneath the well in order to eliminate the influence of noises from circuitry formed in the other regions of the semiconductor substrate 1 (such as for example an input/output circuit as part of peripheral circuitry).

The memory-cell select MISFET Qs of a memory cell may be an n-channel type which is formed in an active region L of the p-type well 2. As shown in Figs. 2 and 3, this active region L is designed to have an elongate island-like shape that linearly extends along the lateral direction (X direction) in the drawings, wherein its size in the X direction is $1.16\mu\text{m}$, whereas the size in the up-down direction (Y direction) is $0.24\mu\text{m}$. In case the active region L is designed into such a simple straight line pattern, a hard-to-resolve ultrafine pattern will no longer take place even when downsizing or miniaturization is done to the extent that is equivalent to a limit of resolvability in photolithography techniques, which makes it possible to achieve good dimension accuracy as required. It is noted here that the dimensions of the active region L and of respective constituent components of a memory cell, as will be discussed later, are mere examples and should not be used for purposes of limiting the interpretation of the present invention.

As shown in Figs. 4(a) and 4(b), an element isolation region surrounding the active region L consists essentially of an element separation groove 5, which may be a shallow groove defined in the p-type well 2 with a silicon oxide film 4 embedded therein. The silicon oxide film 4 buried in the element separation groove 5 is planarized so that its top surface is substantially identical in height to the surface of the active region L-namely the film 4 is flush with active region L. Since the element

isolation region comprised of the element separation groove 5 has no sharp edges known as "bird's beaks" in the semiconductor art at terminate end portions of the active region, the effective area of the active region L may be increased as compared to the same-size element isolation region (field oxide film) formed by the conventional local oxidation of silicon (LOCOS) process (selective oxidation method).

In each active region L, two neighboring memory-cell select MISFETs Qs are formed and aligned in the X direction with either one of the source and drain commonly shaped thereby. One memory-cell select MISFET Qs consists mainly of a gate oxide film 6 and an insulated gate electrode 7 as well as a pair of n-type semiconductor regions 8, 8 forming the source and drain thereof.

As shown in Figs. 2-3, the gate electrode 7 of the memory-cell select MISFET Qs is formed integrally with a corresponding one of the word lines WL to extend linearly in the Y direction up to the terminate end of the memory array with the same width and same distance or interval retained along the length thereof. The width of the gate electrode 7 (word line WL), or gate length, is arranged to have a size (0.24 μ m, for example) capable of suppressing the so-called short-channel effect of the memory-cell select MISFET Qs to thereby allow the threshold voltage to be more than or equal to a pre-specified value. In addition, the distance or interval of two neighboring gate electrodes 7 (word lines WL) is set to be a minimal size determinable by the photolithography resolution limit (0.22 μ m, for example), which is shorter than the gate length of the gate electrode 7 (word line WL). In the case where the gate electrode 7 (word line WL) is designed into such a simple straight line pattern, it is possible to achieve excellent size accuracy even when the distance

thereof is highly miniaturized or shrunk down at the photolithography resolution limit level.

The gate electrode 7 (word line WL) is constituted for example from a multilayer structure (polymetal structure) of a low-resistivity polycrystalline silicon film with a chosen n-type impurity such as for example phosphorus (P) doped therein to
5 and a tungsten (W) film insulatively stacked thereover with a TiN film sandwiched between them. In case the gate electrode 5 (word line WL) is partly comprised of such low-resistivity metal (W), the resultant sheet resistivity may be reduced to approximately 2 Ω/G , which in turn enables suppression of any possible word line
10 delay. Additionally, as such word line delay may be suppressed without backplating the gate electrode 5 (word line WL) by use of any low-resistivity metal lead, it becomes possible to reduce by one the requisite number of those lead layers which are formed to overlie the memory cells involved.

The gate electrodes 7 (word lines WL) are covered at their upper portions by
15 a silicon nitride film 9, wherein another silicon nitride film 10 is formed on the side walls of this silicon nitride film 9 and of gate electrode 7 (word line WL) and also on the surface of the element separation groove 5. A double-layered structure of silicon oxide films 11, 12 is formed to overlie silicon nitride film 9 that covers the gate electrode 7 (word line WL), the upper film 12 of which is planarized in such a
20 manner that its surface is substantially identical in height with respect to an overall surface area of the semiconductor substrate 1.

At a location overlying a pair of n-type semiconductor regions 8 making up the source and drain of a memory-cell select MISFET Qs, contact holes 13 and 14 are formed which extend through the silicon oxide films 12, 11 and gate oxide film 6 to

reach the n-type semiconductor regions 8. These contact holes 13, 14 are filled with plugs (conductive layers) 15 embedded therein, which are made of low-resistivity polysilicon film components with a chosen impurity of n-type conductivity (phosphorus (P), for example) doped therein.

5 The contact holes 13, 14 and the plugs (conductive layers) 15 are formed so that each is self-aligned with the silicon nitride film 10 against the gate electrode 7 (word line WL). More specifically, the diameter of each contact hole 13, 14 at the bottom portion thereof in the X direction is equal in dimension to a distance between the silicon nitride film 10 on the sidewall of one of two neighboring gate electrodes 7
10 (word lines WL) and the silicon nitride film 10 on the sidewall of a remaining one thereof. It is required that the thickness of the silicon nitride film 10 in the X direction be at least a specific film thickness capable of preventing leakage between the plugs (conductive layers) 15 within the contact holes 13, 14 and gate electrodes 7 (word lines WL), which thickness typically measures $0.05\mu\text{m}$. Accordingly, where the
15 interval or pitch of the gate electrodes 7 (word lines WL) is set at a size determinable depending upon the photolithography resolution limit (here, $0.22\mu\text{m}$), the X-directional diameter at the bottom of each contact hole 13, 14 is given as $0.12 (= 0.22 - (0.05 \times 2)) \mu\text{m}$, which is less than the resolution limit even at its maximal value. Additionally the along-the-X-direction diameter at the upper part of each
20 contact hole 13, 14 is set at $0.24\mu\text{m}$, or more or less. In this way, where the contact holes 13, 14 are each formed in self-alignment with the gate electrode 7 (word lines WL), it becomes possible to ensure successful prevention of any electrical shortcircuiting between such contact holes 13, 14 and gate electrodes 7 (word lines WL) is reduced through advanced microfabrication processes down at the

photolithography resolution limit level. In another words, since the contact holes 13, 14 and the plugs 15 (conductive layers) are each formed in self-alignment with the gate electrode 7 (word lines WL), the distance between the word lines can be set to be a minimal size as determined by the resolution limit of the photolithography.

5 The contact hole 14, which is one of the above-noted contact holes 13, 14, has its diameter in the Y direction that is the same as the size ($0.24\mu\text{m}$) of the active region L in the Y direction. In contrast, the along-the-Y-direction diameter of the remaining contact hole (a contact hole overlying the n-type semiconductor region 8 as commonly shared by two memory-cell select MISFETs Qs) 13 is set at a
10 preselected value ($0.48\mu\text{m}$, for example) that is greater than the diameter of the active region L in the Y direction ($0.24\mu\text{m}$). In other words, the contact hole 13 is designed to have a substantially rectangular planar pattern wherein the diameter in the Y direction is greater than the diameter in the X direction (at the upper end portion thereof), part of which is arranged to go out of the active region L and extend
15 up to the upper portion of the element separation groove 5.

 A silicon oxide film 16 is formed to overlie the silicon oxide film 12 with the contact holes 13, 14 formed therein; further, the bit lines BL are formed to overlie it. As shown in Figs. 2-3, the bit lines BL are disposed to overlie the element separation grooves 5 in a manner such that they extend linearly in the X direction up to the
20 terminate end of the memory array with the same width and same intervals kept along the entire length thereof. The pitch of two neighboring bit lines BL is the same as the memory cell size ($0.46\mu\text{m}$) in the X direction.

 The bit lines BL are formed such that the distance or interval therebetween is longer than the width thereof in order to maximally reduce an inherent parasitic or

stray capacitance that will possibly be formed between adjacent ones of the bit lines BL to thereby improve information reading/writing speeds. In other words, letting the bit lines BL decrease in width for widening the distance between neighboring bit lines BL makes it possible to reduce any possible parasitic capacitance. The distance of bit lines BL is typically set at $0.32\mu\text{m}$. In this case the width of each bit line BL is at $0.14\mu\text{m}$ ($= 0.46 - 0.32$), which is less than the minimum size determinable by the photolithography resolution limit value. Where the bit lines BL are designed into such a simple linear pattern, it is possible to attain good size accuracy even when the width thereof is reduced by microfabrication down at the photolithography resolution limit level. In addition, letting the distance of bit lines BL greater than the width thereof makes it possible, even when the memory cell size is shrunk, to reserve the required opening margin of through-going holes (those through-holes each connecting between an information accumulation capacitive element C and its associated contact hole 14) 21 each disposed at an intersection between a bit line BL and its associative gate electrode 7 as will be described later.

The bit lines BL are each constituted from a multilayer structure of a TiN film and an overlying W film laminated over each other. In case part of bit line BL is made of a certain low-resistivity metal (W), its resultant sheet resistivity may be reduced down to about $2\ \Omega/\square$ thereby enabling information reading and writing to be performed at high speeds. In addition, as those on-chip leads of peripheral circuitry of the DRAM are manufacturable simultaneously at a process step of fabricating the bit lines BL, it is possible to simplify the manufacturing processes of such DRAM. Further, in case of bit line BL are comprised of specific materials (W, TiN) of greater electro-migration durability, it is possible to reduce the rate of open-circuit defects

even when miniaturizing the width of the bit lines BL down to a minimal level at or near the photolithography resolution limit level.

The bit lines BL are arranged so that each is electrically connected to the plug (conductive layer) 15 within said contact hole 13 via a through-hole 17 formed in the silicon oxide film 16 and is further electrically coupled through this plug (conductive layer) 15 to the n-type semiconductor region 8 (one of the source and drain) commonly shared by two memory-cell select MISFETs Qs. The through-hole 17 for use in connecting between such bit line BL and its associated plug (conductive layer) 15 within the contact hole 13 is formed immediately beneath the bit line BL disposed so as to overlie the element separation groove 5 and is designed to have a diameter that is greater than the width of bit line BL. In this way, letting the Y-directional diameter of the contact hole 13 be greater than its X-directional diameter, while at the same time causing part of it to extend up to a location overlying the element separation groove 5, may ensure successful electrical connection between the bit line BL and the n-type semiconductor region 8 without having either to partially fatten the width of bit line BL and let it extend up to the location overlying the active region L or to fold part of the active region L in the direction of bit line BL.

Silicon oxide films 18, 19 are provided to overlie the bit lines BL; further, a silicon nitride film 20 is formed to overlie such films. The silicon oxide film 19 is planarized to ensure that its surface is kept substantially identical in height over the entire area of the semiconductor substrate 1. Formed over the silicon nitride film 20 is the information accumulation capacitive element C. The information accumulation capacitive element C is formed of a lamination, called a stacked structure in the art to which the invention pertains, of a lower-side electrode (accumulation electrode)

22 and an intermediate capacitor dielectric film 23, plus an upper-side electrode (plate electrode) 24 in this order of sequence looking at from the lowest layer. The lower electrode 22 and upper electrode 24 are each made of a low-resistivity polysilicon film with a chosen impurity-phosphorus (P) for example opened thereinto, whereas the capacitor dielectric film 23 is an insulative film with high resistivity such as tantalum oxide (Ta_2O_5) by way of example.

As shown in Figs. 2-3, the lower electrode 22 of the information accumulation capacitive element C is designed to have an elongate pattern that linearly extends in the X direction shown in the drawings, wherein it measures $0.77\mu\text{m}$ in size in the X direction and $0.31\mu\text{m}$ in Y direction. Additionally, the distance between neighboring lower electrodes 22 is $0.15\mu\text{m}$ in both the X direction and Y direction. In case the lower electrode 22 is arranged to have such a simple straight line pattern, any resolution-difficult ultrafine patterns will no longer take place even when the distance is reduced down to the photolithography resolution limit level, which in turn makes it possible to attain good size accuracy as required.

The lower electrode 22 of the information accumulation capacitive element C is electrically connected to the plug (conductive layer) 15 residing within said contact hole 14 via a through-hole 21 which is formed to penetrate the silicon nitride film 20 and silicon oxide films 19, 18 plus the underlying silicon oxide film 16 and is further electrically coupled via this plug (conductive layer) 15 to the remaining one of the source and drain of the memory-cell select MISFET Qs. Since the through-hole 21 for use in connecting together the lower electrode 22 and the plug (conductive layer) 15 within the contact hole 14 is laid but between a bit line BL and another bit line BL next thereto, the opening area of such through-hole 21 is determinable by the

distance of bit lines BL. Where the bit lines BL are designed so that each linearly extends in the X direction with the same width and same interval retained along the overall length thereof in the way stated supra, it becomes possible to ensure elimination or preclusion of any unwanted electrical shorting between the lower
5 electrode 22 within the through-hole 21 and its associated bit line(s) BL due to the fact that the required-opening margin of such through-hole 21 is obtainable even when the memory cell size is shrunk.

Although not specifically depicted in the drawings, an interlayer dielectric film is formed to overlie the information accumulation capacitive element C while letting
10 one or a couple of metal leads be formed to overlie such interlayer dielectric film.

An explanation will next be given of one exemplary method of manufacturing the memory cells arranged as discussed above with reference to Fig. 5(a) through Fig. 30(b) in the order of process steps. Note that ion implantation conditions and those values as to thermal processing temperatures in the following explanation are
15 mere examples and thus should not be used for purposes of limiting the interpretation of the invention as disclosed and claimed herein.

Firstly, as shown in Figs. 5(a) and 5(b), a semiconductive substrate 1 of p conductivity type is prepared which is subjected to thermal processing to form a silicon oxide film 30 on the surface thereof; thereafter, a silicon nitride film 31 is
20 deposited by chemical vapor deposition (CVD) techniques on the silicon oxide film 30. Then, on the silicon nitride film 31, a photoresist film 32 is formed to cover an active region and having more than one opening defined therein as an element isolation region, which photoresist film 32 is used as a mask to pattern the silicon nitride film 31.

Next, after having removed away the photoresist film 32, the silicon oxide film 30 and semiconductor substrate 1 are etched with the silicon nitride film 31 being used as a mask therefor, thereby forming a groove 5a in the semiconductor substrate 1 to a depth of approximately 300 to 400 nanometers (nm) as shown in Figs. 6(a) and 6(b).

Next, as shown in Figs. 7(a), 7(b) and 8, a silicon oxide film 4 is deposited by CVD techniques on the semiconductor substrate 1 and is then subject to thermal processing for densification (sintering) at a temperature of about 1,000°C; thereafter, known chemical-mechanical polishing (CMP) techniques are used to abrade or polish this silicon oxide film 4 while allowing the groove 5a to reside inside of it, thereby forming an element separation groove 5 and active region L.

After having effectuated wet etching using hot phosphoric acid for removal of any residual components of the silicon nitride film 31 on the semiconductor substrate 1 in the active region L, in the semiconductor substrate 1 an n-type semiconductor region 3 is formed, as shown in Figs. 9(a) and 9(b); subsequently, a p-type well 2 is fabricated at a shallow portion of this n-type semiconductor region 3. The n-type semiconductor region 3 is manufacturable in the following way. The semiconductor substrate 1 is doped with a chosen impurity, such as phosphorus (P), by ion implantation techniques at a dose of approximately 1×10^{12} atoms per square centimeter (cm^2) with an acceleration energy of 500 to 1,000 kilo-electronvolts (KeV); thereafter, the resultant structure is then subject to thermal processing for activation at a temperature of about 1,000°C. The n-type semiconductor region 3 is continuously formed at a level beneath a plurality of memory cells. In addition, the

p-type well 2 is fabricated in a way such that a specific impurity---here, boron (B)--- is doped by ion implantation techniques into the n-type semiconductor region 3 at a dose of about 1×10^{13} atoms/cm² with an acceleration energy of 200 to 300 KeV; then, the doped boron (B) impurity is activated through thermal processing at a
5 temperature of about 950°C. When this is done, ion implantation of an impurity (typically, boron fluoride or BF₂) is simultaneously performed for adjustment of the threshold voltage of a memory-cell select MISFET Qs at a dose of about 2×10^{12} /cm² with an acceleration energy of 40 KeV or therearound.

As shown in Figs. 10(a), 10(b) and 11, after having removed by wet cleaning
10 techniques any residual components of the silicon oxide film 30 on the surface of the active region L, on the surface of the p-type well 2 of the active region L, a gate oxide film 6 of the memory-cell select MISFET Qs is fabricated; then a gate electrode 7 (word line WL) is formed thereon. The gate oxide film 6 is formed through wet oxidation of the surface of the p-type well 2 at a temperature ranging
15 from 800 to 900°C. The gate electrode 7 (word line WL) may be formed by a method that includes the steps of depositing by CVD techniques a phosphorus (P)-doped polysilicon film 33 on the semiconductor substrate 1, depositing thereon a TiN film 34 and W film 35 by sputtering techniques, further depositing thereon a silicon nitride film 9 by CVD techniques, and thereafter patterning these films
20 through etching treatment with a photoresist film used as a mask therefor. As previously stated, the gate electrode 7 (word line WL) is formed so that it extends like a straight line segment in the Y direction up to the terminate end of a memory array while maintaining an identical width (0.24μm) and equal interval (0.22μm) along the length thereof.

Next, as shown in Figs. 12(a) and 12(b), after completion of fabrication of n-type semiconductor regions 8 (source, drain) in the p-type well 2 of the active region L to thereby form the memory-cell selecting MISFET Qs, CVD techniques are used to deposit on this memory-cell select MISFET Qs a silicon nitride film 10 and two silicon oxide films 11, 12. The n-type semiconductor regions 8 may be formed by a method including the steps of doping by ion implantation a phosphorus (P) impurity into the p-type well at a dose of approximately 1×10^{14} atoms/cm² with an acceleration energy of about 30KeV, and thereafter applying thermal processing thereto at a temperature of about 900°C for activation of the phosphorus (P) impurity doped. The overlying silicon oxide film 12 is planarized to ensure that its surface is virtually, identical in height with respect to the entire area of the semiconductor substrate 1.

Next, as shown in Figs. 13(a) and 13(b), etching is done with a patterned photoresist film 36 used as a mask to remove selected portions of silicon oxide films 12, 11 which the n-type semiconductor regions 8 (source and drain) of each memory-cell select MISFET Qs. This etching process is performed under the condition that the etching rate of silicon oxide films 12, 11 with respect to the silicon nitride 10 becomes greater while preventing unwanted removal of the silicon nitride film 10 overlying the n-type semiconductor regions 8 and element separation groove 5.

Next, as shown in Figs. 14(a), 14(b) and 15, etching is done with the photoresist film 36 used as a mask to remove away selected portions of the silicon nitride film 10 and gate oxide film 6 overlying the n-type semiconductor regions 8 of memory-cell select MISFET Qs to thereby fabricate a contact hole 13 at a location

overlying one of the source and drain and also a contact hole 14 overlying the other of them. As previously discussed, the contact hole 13 is formed into a pattern of substantially rectangular shape with a diameter in the Y direction greater than that in the X direction whereas the contact-hole 14 is formed to have a pattern with its diameter in the Y direction almost equal to that in the X direction. This etching is done under the condition that the etching rate of silicon nitride film 10 relative to certain silicon oxide films (gate oxide film 6 and silicon oxide film 4 within the element separation groove 5) becomes greater, while eliminating deep cutaway of the n-type semiconductor regions 8 and element separation groove 5. This etching is also designed so that the silicon nitride film 10 is anisotropically etched causing a portion of silicon nitride film 10 to reside on the sidewall of a gate electrode 7 (word line WL). Through such etching treatment the contact holes 13, 14 are formed in self-alignment with the silicon nitride film 10 on the sidewall of gate electrode 7 (word line WL). This formation of such contact holes 13, 14 as self-aligned with silicon nitride film 10 may alternatively be carried out by a method including the steps of anisotropically etching in advance the silicon nitride film 10 and then forming a sidewall spacer on the sidewall of gate electrode 7 (word line WL).

Next, after having removed the photoresist film 36, plugs (conductive layers) 15 are formed within the contact holes 13, 14, as shown in Figs. 16(a) and 16(b). These plugs (conductive layers) 15 are manufacturable by depositing on the silicon oxide film 12 a polycrystalline silicon film with an n-type impurity (for example, phosphorus (P)) doped therein by using CVD methods and thereafter applying chemical-mechanical polishing processing to this polysilicon film thereby letting portions thereof reside inside of the contact holes 13, 14. During later thermal

processing at high temperatures, the n-type impurity doped in the polysilicon films constituting the plugs (conductive layers) 15 behaves to out diffuse from the bottom portions of the contact holes 13, 14 into the n-type semiconductor regions 8 (source, drain) thereby lowering the electrical resistivity of such n-type semiconductor regions

5 8.

Next, as shown in Figs. 17(a), 17(b) and 18, CVD methods are used to deposit on the silicon oxide film 12 a silicon oxide film 16; thereafter, the silicon oxide film 16 is etched with a patterned photoresist film 37 used as a mask to thereby form a through-hole 17 overlying the contact hole 13. As previously stated, 10 the through-hole 17 is formed at a location that overlies the element separation groove 5 and is out of the active region L. optionally a plug comprised of a conductive film made of a polysilicon film or W film may be buried in this through-hole 17.

Next, after having removed the photoresist film 37, regularly spaced parallel 15 bit lines BL are fabricated on the silicon oxide film 12 as shown in Figs. 19(a), 19(b) and 20; then, each bit line BL is electrically connected via the through-hole 17 to the contact hole 13. The bit lines BL are fabricatable by depositing a TiN film and W film by sputtering techniques on the silicon oxide film 12 and then patterning these films through etching with a photoresist film used as a mask therefor. As stated supra, 20 the bit lines BL are so formed as to straightly extend along the X direction at an equal width ($0.14\mu\text{m}$) and an equal interval ($0.32\mu\text{m}$).

Next, as shown in Figs. 21(a) and 21(b), CVD techniques are used to deposit silicon oxide films 18, 19 and silicon nitride film 20 covering the bit lines BL. Then, chemical/mechanical polishing is applied to the silicon oxide film 19 for planarization

so that the resulting surface thereof is kept substantially identical in height over the entire area of the semiconductor substrate 1.

Next, as shown in Figs. 22(a) and 22(b), after having deposited on the silicon nitride film 20 a silicon oxide film 38 and a phosphorus (P) impurity-doped polysilicon film 39 by using CVD methods, etching is done with a photoresist film 40 used as a mask to define openings 25 in the polysilicon film 39 at specified locations overlying the contact holes 14. A respective one of these openings 25 is formed to have a minimal size as determinable by a limit of resolution in photolithography.

Next, as shown in Fig. 23, on the side wall of each opening 25, a sidewall spacer 41 made of polysilicon is formed. Formation of the sidewall spacer 41 is aimed at reservation of sufficient opening margins of through-hole 21 as will be formed to underlie the opening 25 at a later process step for prevention of unwanted electrical shorting between the bit lines BL and a lower-side electrode 22 within the through-hole 21. The sidewall spacer 41 is formed by depositing on the polysilicon film 39 a phosphorus (P)-doped polysilicon film by CVD techniques and then applying anisotropic etching to this polysilicon film to have a desired pattern.

Next, as shown in Figs. 24(a), 24(b) and 25, the polysilicon film 39 and sidewall spacers 41 are used as a mask to sequentially etch selected portions of the silicon oxide film 38 and silicon nitride film 20 plus silicon oxide films 19, 18, 16 which underlie openings 25 to thereby form through-holes 21 each overlying a corresponding contact hole 14. Owing to formation of the sidewall spacers 41 on sidewalls of each opening 25, this through-hole 21 has a diameter that is made finer to the extent that it is less than the diameter of opening 25---i.e. smaller than the minimal size determinable by the limit of resolution in photolithography.

Next, as shown in Figs. 26(a) and 26(b), after having deposited an n-type impurity (e.g. phosphorus (P))-doped polysilicon film 42 by the CVD method to cover the polysilicon film 39 and fill the through-holes 21, by similar CVD methods, a silicon oxide film 43 is deposited on this polysilicon film 42.

5 Next, as shown in Figs. 27(a) and 27(b), after having removed certain portions of the silicon oxide film 43 other than those overlying the through-holes 21 with a photoresist film used as a mask, using CVD methods, a phosphorus (P)-doped polysilicon film 44 is deposited so that it overlies the polysilicon film 42 including the upper part and sidewalls of the silicon oxide film 43.

10 Next, as shown in Figs. 28(a) and 28(b), the polycrystalline silicon films 44, 42, 39 are subject to anisotropic etching to allow the polysilicon film 44 to reside on the sidewall of the silicon oxide film 43 while causing the polysilicon films 42, 39 to reside at locations underlying the silicon oxide film 43.

Next, as shown in Figs. 29(a) and 29(b), using wet etching, the silicon oxide
15 film 43 and silicon oxide film 38 are removed to form the lower-side electrode 22 of the information accumulation, capacitive element C. This etching is carried out under the condition that the etching rate of the silicon oxide films 43, 38 with respect to the silicon nitride film 20 becomes greater while at the same time preventing etching of the silicon oxide film 19 underlying the silicon nitride film 20.

20 Next, as shown in Figs. 30(a) and 30(b), deposit on the surface of the lower electrode 22 a high dielectric film such as tantalum oxide (Ta_2O_5) is deposited by CVD methods to thereby fabricate a capacitor insulation film 23 of the information accumulation capacitive element C. Thereafter, a phosphorus (P)-doped polysilicon film is deposited on the capacitor insulation film 23 to form an upper-side electrode

24 of the information accumulation capacitive element C whereby the DRAM memory cells shown in Figs. 2, 3, 4(a) and 4(b) are thus completed.

(Embodiment 2)

Electrical connection between the n-type semiconductor region 8 of a
5 memory-cell selecting MISFET Qs and its associated one of the bit lines BL may alternatively be accomplished in a way which will be described below.

After having first deposited the silicon nitride film 10 and silicon oxide films 11, 12 at a level overlying formation of a memory-cell select MISFET Qs in accordance with the procedure used at the steps shown in Figs. 5(a) through 12(b) Embodiment
10 1, through-holes 46 are fabricated as shown Figs. 31, 32(a) and 32(b) by etching with a photoresist film 45 used as a mask, each of which overlies the n-type semiconductor region 8 (either one of the source and drain) of memory-cell select MISFET Qs. While each through-hole 46 is formed to have a substantially rectangular pattern with its diameter in the Y direction greater than the diameter in
15 the X direction, like the contact hole 13 of Embodiment 1, the through-hole is formed shallower so that its bottom portion is higher in level than gate electrodes 7 (word lines WL).

Next, after having removed the photoresist film 45, as shown in Figs. 33, 34(a) and 34(b), etching with a second photoresist film 47 used as a mask is done to
20 form a contact hole 48 overlying either one of the source and drain of a memory-cell select MISFET Qs and also to form a contact hole 49 overlying the other of them. These contact holes 48, 49 are each formed to have a pattern that causes the diameter in the Y direction to be virtually equal to that in the X direction. In addition, the contact holes 48, 49 are formed by two step etching treatment using the silicon

nitride film 10 as an etching stopper in a way similar to that in fabrication of the contact holes 13, 14 in Embodiment 1 to thereby preclude deep cutaway of the n-type semiconductor regions 8 and element separation groove 5.

Next, after removal of the photoresist film 47, the same methodology as in Embodiment 1 is used to form plugs (conductive layers) 15 within the through-hole 46 and the contact holes 48, 49, as shown in Figs. 35(a) and 35(b).

Next, as shown in Figs. 36(a) and 36(b), the same method as in Embodiment 1 is used to form a silicon oxide film 16 on the silicon oxide film 12; and, after fabrication of through-holes 17 by etching of specified portions of the silicon oxide film 16 overlying the through-holes 46, bit lines BL are formed on the silicon oxide film 16. Where appropriate, a plug comprised of a conductive film such as a polysilicon film or W film may be buried in each through-hole 17. The subsequent process steps are the same as those in Embodiment 1.

According to the manufacturing method in accordance with the illustrative embodiment, in which there is formed on or over the gate electrode 7 (word line WL) the through-hole 46 having its diameter in the Y direction greater than the diameter in the X direction, while forming beneath this through-hole 46 the contact hole 48 with its diameter in the Y direction almost identical to the diameter in the X direction, permits the area in which the plug (conductive layer) 15 buried in the contact hole 48 and the sidewall of the gate electrode 7 (word line WL) oppose each other to become less than that in Embodiment 1. This makes it possible to reduce the parasitic capacitance possibly formed between the plug (conductive layer) 15 and gate electrode 7 (word line WL), which in turn enables suppression of word line delay accordingly.

(Emb diment 3)

The through-hole for use in connecting together the through-hole 14 which is formed to overlie the n-type semiconductor region 8 of a memory-cell select MISFET Qs and the lower electrode 22 of an information accumulation capacitive element C may alternatively be formed in self-alignment with a corresponding one of the bit lines BL.

In this case, after having first formed a contact hole 13 of substantially rectangular shape and a contact hole 14 of almost square shape at locations overlying the source and drain of the memory-cell select MISFET Qs by use of the same method as in Embodiment 1, as shown in Fig. 37 (a schematical plan view of a semiconductor substrate for indication of part of the memory array thereof) and Fig. 38(a) which is a sectional view along line A-A' of Fig. 37 and Fig. 38(b) which is a sectional view along line C-C' of Fig. 37, and then having formed plugs (conductive layers) 15 within them, a silicon oxide film 12 deposited on the contact holes 13, 14 is etched to form a through-hole 17 overlying the element separation groove 5 at a location out of the active region L.

Subsequently, bit lines BL are formed on the silicon oxide film 12; then, electrical connection is effected between the bit lines BL and the plugs (conductive layers) 15 within the contact holes 13 via respective through-holes 17. The bit lines BL are manufacturable by depositing on the silicon oxide film 12 a TiN film and W film by sputtering techniques and then depositing on the W film a silicon nitride film 50 by CVD techniques and thereafter patterning these films through etching with a photoresist film used as a mask therefor. The bit lines BL thus formed are such that they straightly extend in the X direction at an equal interval with an identical width

kept along the length thereof.

The bit lines BL are specifically arranged so that the distance or interval between adjacent ones thereof is greater than the width of each bit line in order to minimize any possible parasitic capacitance formed between neighboring ones of the bit lines BL for improvement of information read/write rates. For instance, the interval of bit lines BL is set at $0.24\mu\text{m}$. At this time, let the pitch of two neighboring bit lines BL--namely the memory cell size in the Y direction---be set at $0.46\mu\text{m}$, which results in the width of a bit line BL being substantially equal to $0.22\mu\text{m}$ ($= 0.46 - 0.24$), which may be about the same as the minimum size determinable by a limit of resolution in photolithography.

Next, as shown in Figs. 39(a) and 39(b), form on respective side walls of bit lines BL sidewall spacers 51 each made of a silicon nitride film; thereafter, use CVD techniques to sequentially deposit on or over the bit lines BL a silicon oxide film 19 and silicon nitride film 20 plus silicon oxide film 38 in this order. The sidewall spacers 51 may be fabricated by anisotropically etching the CVD-deposited silicon nitride film overlying the bit lines BL. The silicon oxide film 38 is subjected to chemical/mechanical polishing processes to ensure that its resultant surface is kept substantially identical with respect to the entire surface area of the semiconductor substrate 1.

Next, as shown in Figs. 40(a) and 40(b), more than one selected portion of the silicon oxide film 38 overlying said contact hole 14 is etched away with a photoresist film 52 used as a mask. This etching process is done under the condition that the etching rate of the silicon oxide film 38 relative to the silicon nitride film 20 becomes greater while preventing removal of the silicon nitride film 20.

Next, as shown in Figs. 41(a) and 41(b), after having removed the silicon nitride film 20 through etching with the photoresist film 52 used as a mask, etch the silicon oxide film 19 and silicon oxide film 16 under the condition that the etching rate relative to the silicon nitride film 50 overlying the bit lines BL and the sidewall spacers 51 comprised of silicon nitride film on the sidewalls thereof becomes greater to thereby form through-holes 53 overlying the contact holes 14 in self-alignment with the bit lines BL.

Thereafter, as shown in Figs. 42(a) and 42(b), fabricate an information accumulation capacitive element C with a stacked structure overlying the through-hole 53 by the same method as that used in Embodiment 1, which element consists essentially of a lamination of a lower-side electrode (charge accumulation electrode) 22 and capacitor dielectric film 23 plus upper-side electrode (plate electrode) 24.

So far, the present invention made by the inventor(s) has been described in detail based on some illustrative embodiments; however, it should be noted that the invention should not be limited only to such embodiments discussed above and may alternatively be modifiable and alterable in a variety of forms without departing from the spirit and scope of the invention.

According to the method of manufacturing a semiconductor of the present invention, it becomes possible to retain the required size/dimension accuracy along with resolution margins of photoresist films while at the same time enabling successful reduction of any limits as to on-chip layout of integrated circuit components. This makes it possible to reduce or "shrink" both the pitch of the gate electrodes (word lines) and the pitch of the bit lines thereby enabling miniaturization

of DRAM memory cells, which leads to an ability to accomplish further enhanced on-chip integration density. Another advantage of the invention lies in the capability of reducing the area of a semiconductor chip, which in turn makes it possible to increase production yields of DRAM devices.
